Abstract

As a strengthening of Hadwiger’s conjecture, Gerards and Seymour conjectured that every graph with no odd \(K_t\) minor is \((t - 1)\)-colourable. We prove two weaker variants of this conjecture. Firstly, we show that for each \(t \geq 2\), every graph with no odd \(K_t\) minor has a partition of its vertex set into \(6t - 9\) sets \(V_1, \ldots, V_{6t-9}\) such that each \(V_i\) induces a subgraph of bounded maximum degree. Secondly, we prove that for each \(t \geq 2\), every graph with no odd \(K_t\) minor has a partition of its vertex set into \(10t - 13\) sets \(V_1, \ldots, V_{10t-13}\) such that each \(V_i\) induces a subgraph with components of bounded size. The second theorem improves a result of Kawarabayashi (2008), which states that the vertex set can be partitioned into \(496t\) such sets.

1. Introduction

Every graph in this paper is finite and simple. For a non-negative integer \(k\), a graph \(G\) is (properly) \(k\)-colourable if there are \(k\) pairwise disjoint sets \(V_1, \ldots, V_k\) with \(V(G) = \bigcup_{i=1}^k V_i\) such that \(V_i\) induces a subgraph of maximum degree 0 for \(1 \leq i \leq k\).

In 1943, Hadwiger [11] proposed the following question, which is called ‘Hadwiger’s conjecture’, one of the deepest conjectures in graph theory. For more on this conjecture and its variants, readers are referred to the recent survey of Seymour [27].

Conjecture 1.1. (Hadwiger [11]). For each integer \(t \geq 1\), every graph with no \(K_t\) minor is \((t - 1)\)-colourable.

Robertson, Seymour and Thomas [26] proved that the conjecture is true for \(t \leq 6\), but the conjecture remains open for \(t \geq 7\). Kostochka [20, 21] and Thomason [28, 29] proved that graphs with no \(K_t\) minor are \(O(t\sqrt{\log t})\)-colourable, by showing that these graphs contain a vertex of degree \(O(t\sqrt{\log t})\). It is still open whether every graph with no \(K_t\) minor is \(ct\)-colourable for some \(c > 0\) independent of \(t\).

Gerards and Seymour (see [15, Section 6.5]) proposed the following odd-minor variant of Hadwiger’s conjecture.

Conjecture 1.2. (Gerards and Seymour (see [15, Section 6.5])). For each integer $t \geq 1$, every graph with no odd $K_t$ minor is $(t-1)$-colourable.

Catlin [2] proved this conjecture for $t = 4$, and Guenin [10] announced a proof for $t = 5$, but the proof has not been written. Geelen, Gerards, Reed, Seymour and Vetta [8] proved that every graph with no odd $K_t$ minor is $O(t^{\sqrt{\log t}})$-colourable.

A defective colouring (see [3, 31]) is a colouring that relaxes the degree condition. A graph $G$ is $k$-colourable with defect $d$ if there are $k$ pairwise disjoint sets $V_1, \ldots, V_k$ with $V(G) = \bigcup_{i=1}^{k} V_i$ such that every $V_i$ induces a subgraph of maximum degree at most $d$. Note that $G$ is $k$-colourable if and only if $G$ is $k$-colourable with defect 0. A clustered colouring is a colouring that relaxes the size of monochromatic components. A graph $G$ is $k$-colourable with clustering $M$ if there are $k$ pairwise disjoint sets $V_1, \ldots, V_k$ with $V(G) = \bigcup_{i=1}^{k} V_i$ such that every $V_i$ induces a subgraph having no component with more than $M$ vertices.

We present two theorems, both of which are relaxations of Conjecture 1.2 for graphs with no odd $K_t$ minor. Our first theorem is about defective colouring.

Theorem 1.3. For each integer $t \geq 2$, there exists an integer $s = s(t)$ such that every graph $G$ with no odd $K_t$ minor is $(6t - 9)$-colourable with defect $s$.

We remark that the number $6t - 9$ of colours cannot be reduced to a number less than $t - 1$ (see Theorem 2.1).

Our second theorem is about clustered colouring. Kawarabayashi [17] proved that the class of graphs with no odd $K_t$ minor has clustered chromatic number at most $496t$.

Theorem 1.4. (Kawarabayashi [17]). For each integer $t \geq 2$, there is an integer $C = C(t)$ such that every graph $G$ with no odd $K_t$ minor is $496t$-colourable with clustering $C$.

We improve $496t$ to $10t - 13$ as follows.

Theorem 1.5. For each integer $t \geq 2$, there exists an integer $C = C(t)$ such that every graph $G$ with no odd $K_t$ minor is $(10t - 13)$-colourable with clustering $C$.

We also remark that $10t - 13$ cannot be reduced to a number less than $t - 1$. Neither Theorem 1.3 nor Theorem 1.5 can be extended for list-colourings, which we will discuss in Section 6.

The paper is organized as follows. In Section 2 we review related results on minors, some of which will be used in our proof. We briefly introduce some basic notions in Section 3, discuss the structure of graphs with no odd $K_t$ minor in Section 4, and prove Theorems 1.3 and 1.5 in Section 5. In Section 6, we make some further remarks, including extension of our main results to a slightly larger class of graphs. The Appendix reviews elementary concepts of signed graphs and minors.

2. Previous results on improper colouring and forbidden minors

There are many studies regarding improper colourings of graphs with forbidden minors. Kawarabayashi and Mohar [18] proved that the clustered chromatic number of the class of graphs...
with no \(K_t\) minor is at most \([31/2]t\]. This was improved to \([7t - 3]/2\) by Wood \[30\]. Edwards, Kang, Kim, Oum and Seymour \[6\] investigated defective colouring of graphs with no \(K_t\) minor, and proved that the defective chromatic number of the graphs with no \(K_t\) minor equals \(t - 1\).

**Theorem 2.1.** (Edwards, Kang, Kim, Oum and Seymour \[6\]). For each integer \(t \geq 1\), there exists an integer \(s(t) = O(t^2 \log t)\) such that every graph \(G\) with no \(K_t\) minor is \((t - 1)\)-colourable with defect \(s(t)\). Moreover, this is sharp in the sense that we cannot reduce the number \(t - 1\) of colours to \(t - 2\).

They also proved that the clustered chromatic number of the class of graphs with no \(K_t\) minor is at most \(4t - 4\). Liu and Oum \[22\] proved that for every graph \(H\), every graph \(G\) with no \(H\) minor and maximum degree at most \(\Delta\) is 3-colourable with clustering \(f(H, \Delta)\) for some function \(f\), which generalises the result of Esperet and Joret \[7\] for graphs embeddable on surfaces of bounded Euler genus. Combined with Theorem 2.1, this implies that the clustered chromatic number of the class of graphs with no \(K_t\) minor is at most \(3t - 3\). Van den Heuvel and Wood \[13\] proved that every graph with no \(K_t\) minor is \((2t - 2)\)-colourable with clustering \([\lceil (t - 2)/2\rfloor\), using a different proof that does not rely on the excluded minor structure theorem. Dvořák and Norin \[5\] proved that the clustered chromatic number of the class of graphs with no \(K_t\) minor and treewidth at most \(w\) is at most \(t - 1\), and announced that the clustered chromatic number of the class of graphs with no \(K_t\) minor equals \(t - 1\).

What happens if the forbidden graph \(H\) is not complete? Let \(I_t\) be a graph on \(t\) vertices with no edges, and for graphs \(G\) and \(H\), let \(G + H\) be a graph obtained from the disjoint union of \(G\) and \(H\) by adding an edge between each vertex of \(G\) and each vertex of \(H\). For positive integers \(s\) and \(t\), let \(K_{s,t}^*\) be a graph obtained from \(K_s + I_t\) by subdividing every edge joining vertices of the subgraph \(K_s\) once. Recently, Ossona de Mendez, Oum and Wood \[25\] investigated defective colouring for various graph classes. One of their results implies the following, which extends Theorem 2.1 to a larger class of graphs.

**Theorem 2.2.** (Ossona de Mendez, Oum and Wood \[25\]). For integers \(s, t \geq 1\) and real numbers \(\delta_1, \delta_2 > 0\), there exists \(M = M(s, t, \delta_1, \delta_2)\) such that every graph \(G\) satisfying the following three conditions is \(s\)-colourable with defect \(M\).

1. \(G\) contains no \(K_{s,t}^*\) as a subgraph.
2. Every subgraph of \(G\) has average degree at most \(\delta_1\).
3. For every graph \(H\) whose 1-subdivision is a subgraph of \(G\), the average degree of \(H\) is at most \(\delta_2\).

Moreover, this is sharp in the sense that we cannot reduce the number \(s\) to \(s - 1\).

Since \(K_{s,t}^*\) is a bipartite \(K_s + I_t\) subdivision, Theorem 2.2 implies that the defective chromatic number of the class of graphs with no bipartite \(K_s + I_t\) subdivision equals \(s\) as follows. (The lower bound is obtained by Theorem 2.1.)

**Corollary 2.3.** For positive integers \(s\) and \(t\), there is an integer \(N = N(s, t)\) such that every graph \(G\) with no bipartite \(K_s + I_t\) subdivision is \(s\)-colourable with defect \(N\).

**Proof.** By \[1, 19\], there is \(c_0 > 0\) such that for each integer \(p \geq 1\), every \(n\)-vertex graph with average degree at least \(c_0 p^2\) contains \(K_p\) as a topological minor. Since \(G\) contains no bipartite \(K_s + I_t\) subdivision, the graph \(G\) contains no \(K_{s,t}^*\) as a subgraph, and no bipartite \(K_{s+t}\) subdivision. If there is a subgraph \(H\) of \(G\) with average degree at least \(2c_0(s + t)^2\), then let \(H_0\) be a bipartite spanning
subgraph of \( H \) with at least \(|E(H)|/2 \) edges. Since \( H_0 \) has average degree at least \( c_0(s + t)^2 \), it follows that \( H \) contains a bipartite \( K_{s+t} \) subdivision, contradicting the assumption on \( G \). Hence every subgraph of \( G \) has average degree at most \( 2c_0(s + t)^2 \). If there is a graph \( H \) whose 1-subdivision is a subgraph of \( G \), then the average degree of \( H \) is at most \( c_0(s + t)^2 \), because otherwise \( H \) contains \( K_{s+t} \) as a topological minor, and its 1-subdivision is bipartite.

By Theorem 2.2, \( G \) is \( s \)-colourable with defect \( M(s, t, 2c_0(s + t)^2, c_0(s + t)^2) \).

Since \( K_t + I_1 \) is isomorphic to \( K_{t+1} \), Theorem 2.1 can be extended to graphs with no bipartite clique subdivision.

**Corollary 2.4.** For each integer \( t \geq 1 \), the defective chromatic number of the class of graphs with no bipartite \( K_{t+1} \) subdivision equals \( t \).

Mohar, Reed and Wood [23] studied clustered colourings of graphs with no \( C_{k+1} \) minor, where \( C_{k+1} \) denotes a cycle of length \( k + 1 \). They proved that for every integer \( k \geq 2 \), every graph with no \( C_{k+1} \) minor is \( [3 \log_2 k] \)-colourable with clustering \( k \), and the number of colours is asymptotically tight. Norin, Scott, Seymour and Wood [24] proved that for every graph \( H \), the clustered chromatic number of the class of \( H \)-minor-free graphs is tied to the tree-depth of \( H \), giving a partial answer to a conjecture in [25].

Liu and Oum [22] proved that for every graph \( H \) and every integer \( \Delta \), the class of graphs with no odd \( H \) minor and maximum degree at most \( \Delta \) has the clustered chromatic number at most 3.

**Theorem 2.5.** (Liu and Oum [22]). For every graph \( H \) and every integer \( \Delta \geq 0 \), there is \( C = C(H, \Delta) \) such that for every graph \( G \) with maximum degree at most \( \Delta \) and no odd \( H \) minor, there are pairwise disjoint subsets \( V_1, V_2, V_3 \) of \( V(G) \) such that \( V_1 \cup V_2 \cup V_3 = V(G) \) and every component of \( G[V_1] \) has at most \( C \) vertices for \( i = 1, 2, 3 \).

### 3. Preliminaries

We follow the definitions in [4] unless stated otherwise. In this section, \( G \) and \( H \) always denote graphs. For each integer \( N \geq 0 \), let \([N]\) be the set \( \{1, \ldots, N\} \). If \( N = 0 \), then \([N]\) is an empty set. For a graph \( H \), let \( \Delta(H) \) be the maximum degree of vertices in \( H \). For \( S \subseteq V(H) \), let \( H[S] \) be the subgraph of \( H \) induced by \( S \).

A subset \( S \subseteq V(G) \) is stable if no two vertices in \( S \) are adjacent. Let \( G \cup H \) and \( G \cap H \) be graphs \( (V(G) \cup V(H), E(G) \cup E(H)) \) and \( (V(G) \cap V(H), E(G) \cap E(H)) \), respectively. A pair \((A, B)\) of subgraphs of \( G \) is a separation of \( G \) if \( G = A \cup B \). The order of a separation \((A, B)\) of \( G \) is \(|V(A \cap B)|\). A bipartition \((X, Y)\) of a bipartite graph \( H \) is a set of two disjoint stable subsets such that \( X \cup Y = V(G) \).

**Colouring.** For a subset \( S \) of vertices of \( G \) and a set \( T \) of colours, a function \( \alpha : S \rightarrow T \) is a colouring on \( S \). A colour class of a colouring \( \alpha : S \rightarrow T \) is \( \alpha^{-1}(i) \) for some \( i \in T \). A subgraph \( H \) of \( G \) is monochromatic if every vertex of \( H \) has the same \( \alpha \) value.

A colouring \( \alpha \) on \( S \) is proper if \( \alpha(u) \neq \alpha(v) \) for every \( uv \in E(G[S]) \); equivalently, every colour class of \( \alpha \) is stable. For a non-negative integer \( k \), a graph \( G \) is \( k \)-colourable if there is a proper colouring \( \alpha : V(G) \rightarrow [k] \). For integers \( k, d \geq 0 \), a graph \( G \) is \( k \)-colourable with defect \( d \) if there is a colouring \( \alpha : V(G) \rightarrow [k] \) such that every colour class induces a graph with maximum degree at most \( d \), and \( G \) is \( k \)-colourable with clustering \( d \) if there is a colouring \( \alpha : V(G) \rightarrow [k] \) such that every colour class induces a subgraph with no connected components having more than \( d \) vertices.
Paths. A path is a graph that consists of $k$ vertices $v_1, \ldots, v_k$ for some integer $k \geq 1$ and $k - 1$ edges $v_1 v_2, \ldots, v_{k-1} v_k$. The vertices $v_1$ and $v_k$ are called ends, and all other vertices $v_2, \ldots, v_{k-1}$ are called internal vertices.

The path $P$ joins $u, v \in V(G)$ if $u$ and $v$ are ends of $P$. For vertices $v, w \in V(P)$, $P(v, w)$ denotes the subpath of $P$ with the ends $v$ and $w$.

A path $P$ joins two sets $V_1, V_2 \subseteq V(G)$ if it joins a vertex in $V_1$ and a vertex in $V_2$. The length of a path is its number of edges. The parity of a path $P$ is the parity of its length.

Two paths $P$ and $Q$ in $G$ are vertex-disjoint if $V(P) \cap V(Q) = \emptyset$. They are internally disjoint\(^1\) if every common vertex of $P$ and $Q$ is an end of both $P$ and $Q$.

For $S \subseteq V(G)$, an $S$-path is a path in $G$ that joins two distinct vertices in $S$. For a colouring $\alpha : S \to \{1, 2\}$, an $S$-path $P$ from $u$ to $v$ in $G$ is parity-breaking with respect to $\alpha$ if

$$|E(P)| \neq \alpha(u) - \alpha(v) \pmod{2}.$$ 

For a connected bipartite subgraph $H$ of $G$ with a proper colouring $\beta : V(H) \to \{1, 2\}$, a $V(H)$-path $P$ in $G$ is parity-breaking with respect to $H$ if $P$ is parity-breaking with respect to $\beta$. This is well-defined since a proper colouring of $H$ is unique up to permuting colours. We will use the following observation in Section 4.

**Observation 3.1.**

1. For $S \subseteq V(G)$ and a colouring $\alpha : S \to \{1, 2\}$, let $P, Q$ be internally disjoint $S$-paths sharing precisely one end. Then the $S$-path $P \cup Q$ is parity-breaking with respect to $\alpha$ if and only if exactly one of $P$ and $Q$ is parity-breaking with respect to $\alpha$.

2. For a connected bipartite subgraph $H$ of $G$, no path in $H$ is parity-breaking with respect to $H$.

Minors. A graph $H$ is a minor of $G$ if a graph isomorphic to $H$ can be obtained from $G$ by deleting vertices or edges and contracting edges. If there are edges $wu$ and $wv$ for some vertex $w \notin \{u, v\}$ and we contract an edge $uv$, then one of these two edges is removed after contraction to avoid parallel edges. A graph $G$ contains an $H$ minor (or $H$ as a minor) if $H$ is a minor of $G$.

Topological minors. An $H$-subdivision is a graph obtained from $H$ by subdividing edges, where edges may be subdivided more than once. A graph $G$ contains an $H$-subdivision (or $H$ as a topological minor), if $G$ contains a subgraph isomorphic to an $H$-subdivision.

Since every $H$-subdivision $H'$ is built from $H$ by replacing all edges of $H$ with internally disjoint paths called the linking paths, there are vertices of $H'$ that correspond to vertices of $H$, which we call branch vertices.

Odd minors. For $S \subseteq V(G)$ and a colouring $\alpha : S \to \{1, 2\}$, an edge $uv \in E(G[S])$ is bichromatic if $\alpha(u) \neq \alpha(v)$ and monochromatic otherwise.

For graphs $G$ and $H$, $G$ contains $H$ as an odd minor if there exist vertex-disjoint subgraphs $\{T_u\}_{u \in V(H)}$ in $G$ which are trees, and a colouring $\alpha : \bigcup_{u \in V(H)} V(T_u) \to \{1, 2\}$ such that for every $u \in V(H)$, every edge in $T_u$ is bichromatic, and for every edge $vw \in E(H)$, there is a monochromatic edge $e \in E(G)$ that joins $V(T_v)$ and $V(T_w)$.

We will use the following alternative definition in Section 4.

\(^1\)It is called independent in [4].
Observation 3.2. For graphs $G$ and $H$, $G$ contains $H$ as an odd minor if and only if there exist vertex-disjoint subgraphs $\{T_u\}_{u \in V(H)}$ in $G$ which are trees, and a colouring $\alpha : \bigcup_{u \in V(H)} V(T_u) \to \{1, 2\}$ such that:

1. for every $u \in V(H)$, every edge in $T_u$ is bichromatic,
2. there are internally disjoint paths $\{P_e\}_{e \in E(H)}$ in $G$,
3. for every $e = vw \in E(H)$, $P_e$ joins $V(T_v)$ and $V(T_w)$, has no internal vertex in $\bigcup_{u \in V(H)} V(T_u)$, and is parity-breaking with respect to $\alpha$.

We remark that for two graphs $G$ and $H$, $G$ contains $H$ as an odd minor if and only if a signed graph $(G, E(G))$ contains a signed graph $(H, E(H))$ as a minor, which we will discuss in the Appendix.

4. The structure of graphs with no odd clique minor

The proof of Theorem 2.1 is based on the fact that every graph with no $K_t$ minor has a vertex of degree at most $c_t$ for some $c_t$. In contrast to graphs with no $K_t$ minor, graphs with no odd $K_t$ minor may have arbitrarily large minimum degree; for example, complete bipartite graphs have no odd $K_3$ minor.

To prove Theorems 1.3 and 1.5, we use the following strategy similar to the one by Geelen, Gerards, Reed, Seymour and Vetta [8]. If a graph $G$ has no bipartite subdivision of some graph, then we apply Corollary 2.3. Otherwise, we will show in Theorem 4.5 that $G$ contains a bipartite block after removing few vertices, which allows us to use precolouring arguments in the following section.

First of all, we describe how to find an odd $K_t$ minor in a graph $G$ if the graph contains a bipartite $K_{2t-2} + I_t$ subdivision with many vertex-disjoint parity-breaking paths between branch vertices of the subdivision.

Lemma 4.1. For $t \geq 2$, let $G$ be a graph that contains a bipartite $K_{2t-2} + I_t$ subdivision $H$, and let $C$ be the set of all branch vertices of $K_{2t-2} + I_t$ in $H$. If there are $t-1$ vertex-disjoint parity-breaking $C$-paths with respect to $H$, then $G$ contains an odd $K_t$ minor.

Proof. For convenience, we identify each vertex in $C$ with its corresponding vertex of $K_{2t-2} + I_t$.

For a collection $Q$ of paths, let $\ell(Q) = \sum_{P \in Q} |E(P)|$. Let $\mathcal{P}$ be a collection of $t-1$ vertex-disjoint parity-breaking $C$-paths with respect to $H$, satisfying the following:

(a) $\sum_{P \in \mathcal{P}} |E(P) \setminus E(H)|$ is minimum, and
(b) subject to (a), $\ell(\mathcal{P})$ is minimum.

Note that no vertex in $C$ is an internal vertex of a path in $\mathcal{P}$. To see this, if a vertex in $C$ is an internal vertex of a path $Q \in \mathcal{P}$, then $Q$ contains a proper subpath $Q'$ that is a parity-breaking $C$-path with respect to $H$. For $Q := (\mathcal{P} \setminus \{Q\}) \cup \{Q'\}$ it follows that

$$\sum_{P \in Q} |E(P) \setminus E(H)| \leq \sum_{P \in \mathcal{P}} |E(P) \setminus E(H)|$$

and $\ell(Q) < \ell(\mathcal{P})$, contradicting our choice of $\mathcal{P}$.

For distinct $u, v \in C$, if $uv \in E(K_{2t-2} + I_t)$, then let $Q_{u,v}$ be the linking path from $u$ to $v$ in $H$. If $uv \notin E(K_{2t-2} + I_t)$, then let $Q_{u,v}$ be a graph with two vertices $u$ and $v$ and no edges. Note that there are $2t - 2$ branch vertices that appear in paths in $\mathcal{P}$, and $t$ unused branch vertices. Let $C_0 \subseteq C$ be the set of those unused $t$ branch vertices.
Claim 1. Let \( u, v \) be distinct vertices in \( C \).

1. If \( u, v \in C_0 \), then no path \( P \in \mathcal{P} \) intersects \( Q_{u,v} \).
2. If \( u \in C_0 \), then \( Q_{u,v} \) intersects at most one path \( P \in \mathcal{P} \), and if so, then the intersection is a subpath of both \( Q_{u,v} \) and \( P \) and contains \( v \).

Proof of Claim 1. We may assume \( uv \in E(K_{2t-2} + I_t) \), otherwise \( V(Q_{u,v}) \subseteq C \) and the claim is trivial. Let \( u \in C_0 \), and suppose \( Q_{u,v} \) intersects a path in \( \mathcal{P} \). Since no path in \( \mathcal{P} \) intersects \( u \), starting from \( u \) and following \( Q_{u,v} \) we arrive at the first vertex \( w \in V(Q_{u,v}) \) on some path \( P \in \mathcal{P} \).

Write \( P = A \cup B \), where \( A \) and \( B \) are two subpaths of \( P \) with the only common vertex \( w \). Since \( w \in V(H) \), either \( A \) or \( B \) is parity-breaking with respect to \( H \), and we may assume \( A \) is parity-breaking with respect to \( H \). By Observation 3.1, a path \( R = A \cup Q_{u,v}(w, u) \) is parity-breaking with respect to \( H \), and it intersects no path in \( \mathcal{P} \) other than \( P \). Therefore, we conclude that \( (\mathcal{P} \setminus \{P\}) \cup \{R\} \) is a set of \( t - 1 \) vertex-disjoint parity-breaking \( C \)-paths with respect to \( H \). By our assumption on \( \mathcal{P} \), \( P \) does not have more edges not in \( H \) than \( R \). This implies \( E(B) \subseteq E(H) \), and thus \( B = Q_{u,v}(w, v) \) since one of the ends of \( B \) is in \( C \) and no path in \( \mathcal{P} \) intersects \( u \). Note that \( A \) intersects \( Q_{u,v} \) only at \( w \), since \( B = Q_{u,v}(w, v) \).

Since \( P \) and \( Q_{u,v} \) share a common subpath from \( w \) to \( v \) and \( w \) is the only vertex that belongs to both \( Q_{u,v}(w, u) \) and some path in \( \mathcal{P} \), \( P \) is the only path that intersects \( Q_{u,v} \). In particular, if \( B = P \cap Q_{u,v} \) is a path that contains \( v \), and \( v \notin C_0 \). \( \square \)

Let \( \mathcal{P} = \{P_1, \ldots, P_{t-1}\} \), and for \( 1 \leq i \leq t - 1 \), let \( x_i \) and \( y_i \) be the ends of \( P_i \). Let \( C_1 = \{x_1, \ldots, x_{t-1}\} \) and \( C_2 = \{y_1, \ldots, y_{t-1}\} \).

For \( v \in C \), if \( v \) corresponds to a vertex in the subgraph \( K_{2t-2} \) of \( K_{2t-2} + I_t \), then we call \( v \) Type-A. Otherwise we call \( v \) Type-B. Let \( q \) be the number of \( i \) \((1 \leq i \leq t - 1) \) such that both \( x_i \) and \( y_i \) are Type-A, and \( r \) be the number of \( i \) such that exactly one of \( x_i \) and \( y_i \) is Type-A, and \( s = t - 1 - q - r \). Then there are \((2t - 2) - (2q + r)\) vertices of Type-A in \( C_0 \). Since \( q + r + s = t - 1 \), it follows that \((2t - 2) - (2q + r) \geq r + s \). Therefore, the number of vertices in \( C_0 \) of Type-A is at least \( r + s \).

Thus, we choose an ordering \( z_1, \ldots, z_t \) of the vertices in \( C_0 \) such that for \( 1 \leq i \leq t - 1 \) if \( x_i \) or \( y_i \) is Type-B, then \( z_i \) is a vertex of Type-A.

In summary, \( z_iz_{i+1}z_{i+2} \in E(K_{2t-2} + I_t) \) for \( 1 \leq i \leq t - 1 \). Equivalently, if \( z_i \) is Type-B, then both \( x_i \) and \( y_i \) are Type-A.

Let \( \beta : V(H) \to \{1, 2\} \) be a proper colouring of \( H \) unique up to permuting colours. In order to find an odd \( K_t \) minor, we now aim to construct vertex-disjoint subgraphs \( M_1, \ldots, M_t \) in \( G \) which are trees and a colouring \( \alpha : \bigcup_{i=1}^t V(M_i) \to \{1, 2\} \) as in Observation 3.2.

For \( 1 \leq i \leq t - 1 \), let \( M_i = P_i \cup Q_{z_i,y_i} \) if \( z_i \) is Type-A, and \( M_i = P_i \cup Q_{z_i,x_i} \) if \( z_i \) is Type-B. Let \( M_t \) be a graph with the only vertex \( z_t \). If \( i \leq t \), then by Claim 1, \( P_i \cap Q_{z,x} \) or \( P_i \cap Q_{z,y} \) is a subpath of \( P_i \), and \( M_t \) is a tree with maximum degree at most 3 and at most one vertex of degree 3. We choose a colouring \( \alpha : \bigcup_{i=1}^t V(M_i) \to \{1, 2\} \) such that

1. \( \alpha \) on \( V(M_i) \) is a proper colouring of \( M_i \) and \( \alpha(x_i) = \beta(x_i) \) for all \( 1 \leq i \leq t - 1 \), and
2. \( \alpha(z_t) = \beta(z_t) \) if and only if \( z_t \) is Type-B.

Observation 3.1 implies that, for \( 1 \leq i \leq t - 1 \), \( \alpha(y_i) \neq \beta(y_i) \) since \( P_i \) is parity-breaking with respect to \( H \) and \( \alpha(z_t) = \beta(z_t) \) if and only if \( z_t \) is Type-B.

For \( 1 \leq i < j \leq t \), we are now ready to construct a path \( P_{ij} \) joining \( V(M_i) \) and \( V(M_j) \) that is parity-breaking with respect to \( \alpha \) and satisfies Observation 3.2. This will show that \( G \) contains an odd \( K_t \) minor. The structure of \( P_{ij} \) depends on the types of \( z_i \) and \( z_j \).

---

2 Two subgraphs intersect if they share at least one common vertex.
Case 1. Both $z_i$ and $z_j$ are Type-A.

Following $Q_{z_j,x_i}$ from $z_j$ to $x_i$, we arrive at the first vertex $a_{ij}$ in $V(P_i) \cap V(Q_{z_j,x_i})$. By Claim 1, $Q_{z_j,x_i}$ and $P_i$ share the subpath from $a_{ij}$ to $x_i$. Since $P_i(x_i, a_{ij})$ is in $H$ and $\alpha(x_i) = \beta(x_i)$, it follows that $\alpha(a_{ij}) = \beta(a_{ij})$ by Observation 3.1. Let us define $P_{ij} = Q_{z_j,x_i}(a_{ij}, a_{ij})$. Since $\alpha(z_j) \neq \beta(z_j)$, $\alpha(a_{ij}) = \beta(a_{ij})$ and $P_{ij}$ is a subpath of $Q_{z_j,x_i}$, we conclude that $P_{ij}$ is parity-breaking with respect to $\alpha$ by Observation 3.1.

Case 2. $z_i$ and $z_j$ are of different types.

Let us define $P_{ij} = Q_{z_i,z_j}$. By Claim 1, $P_{ij}$ intersects no path in $P$. Since $\alpha(z_i) = \beta(z_i)$, $\alpha(z_j) \neq \beta(z_j)$, and $Q_{z_i,z_j}$ is in $H$, $P_{ij}$ is parity-breaking with respect to $\alpha$ by Observation 3.1.

Case 3. Both $z_i$ and $z_j$ are Type-B.

Since $z_i$ is Type-B, $y_i$ is Type-A. Following $Q_{z_i,y_i}$ from $z_i$ to $y_i$, we arrive at the first vertex $a_{ij}$ in $V(P_j) \cap V(Q_{z_i,y_i})$. Claim 1 implies that $Q_{z_i,y_i}$ and $P_j$ share the subpath from $a_{ij}$ to $y_i$. Since $P_j(y_i, a_{ij})$ is in $H$ and $\alpha(y_i) \neq \beta(y_i)$, it follows that $\alpha(a_{ij}) \neq \beta(a_{ij})$. Let us define $P_{ij} = Q_{z_i,y_i}(a_{ij}, a_{ij})$. Since $\alpha(z_j) = \beta(z_j)$, $\alpha(a_{ij}) \neq \beta(a_{ij})$ and $P_{ij}$ is in $H$, $P_{ij}$ is parity-breaking with respect to $\alpha$ by Observation 3.1.

We use the following lemma, which asserts that the family of $S$-paths of odd length satisfies the Erdős–Pósa property.

Lemma 4.2. (Geelen, Gerards, Reed, Seymour and Vetta [8, Lemma 11]). Let $G$ be a graph and $S \subseteq V(G)$. For every integer $\ell \geq 1$, $G$ contains $\ell$ vertex-disjoint $S$-paths of odd length, or there is $X \subseteq V(G)$ with $|X| \leq 2\ell - 2$ such that $G \setminus X$ contains no $S$-path of odd length.

Observation 4.3. Let $G$ and $H$ be graphs and $X \subseteq V(G)$. If $G$ contains an $H$-subdivision $K$, then $G \setminus X$ contains an $H'$-subdivision $K'$ such that $H' = H \setminus Y$ for some $Y \subseteq V(H)$ with $|Y| \leq |X|$ and $K'$ is a subgraph of $K$.

Proof. It is easy to see that if $G$ has an $H$-subdivision $K$ and $v$ is a vertex of $K$, then there is a vertex $w$ of $H$ such that $G \setminus v$ has a $(H \setminus w)$-subdivision.

The following lemma is a variation of [8, Lemma 15].

Lemma 4.4. Let $\ell$ be a positive integer and $G$ be a graph. Let $H$ be a bipartite $K_s + I_t$ subdivision in $G$ for integers $s \geq 2\ell$ and $t \geq 1$, and $C$ be the set of all branch vertices in $H$. At least one of the following holds.

- There exists $X \subseteq V(G)$ with $|X| \leq 2\ell - 2$ such that $G - X$ has a bipartite block $U$ that contains at least $s + t - |X|$ vertices in $C \setminus X$ and all linking paths in $H$ between them.
- $G$ has $\ell$ vertex-disjoint parity-breaking $C$-paths with respect to $H$.

Proof. (1) We claim that either there are $\ell$ vertex-disjoint parity-breaking $C$-paths in $G$ with respect to $H$, or there is $X \subseteq V(G)$ with $|X| \leq 2\ell - 2$ such that $G \setminus X$ contains no parity-breaking $C$-path with respect to $H$. 

Let \( \{L, R\} \) be the unique bipartition of \( H \). Without loss of generality, we may assume that every linking path corresponding to an edge in \( K_s + I_t \) has even length, because otherwise, for every branch vertex \( v \in C \cap L \), we subdivide each edge \( e \in E(G) \) incident with \( v \) once. This gives an \( H \)-subdivision \( H' \) and a \( G \)-subdivision \( G' \) such that \( H' \) is a bipartite subgraph of \( G' \). We may assume \( V(H) \subseteq V(H') \) and \( V(G) \subseteq V(G') \), and then every vertex in \( V(G') \setminus V(G) \) has degree 2. Note that all vertices in \( C \) are in the same part of the bipartition of \( H' \), and thus every path in \( H' \) between vertices in \( C \) has even length. It is easy to check the following.

- A \( C \)-path of odd length in \( G' \) corresponds to a parity-breaking \( C \)-path in \( G \) with respect to \( H \).
- If there is \( X' \subseteq V(G') \) with \( |X'| \leq 2\ell - 2 \) such that \( G' \setminus X' \) contains no \( C \)-path of odd length, then we may assume \( X' \subseteq V(G) \) since every vertex in \( V(G') \setminus V(G) \) has degree 2.

Lemma 4.2 claims that either \( G' \) contains \( \ell \) vertex-disjoint \( C \)-paths of odd length, or there is \( X' \subseteq V(G') \) with \( |X'| \leq 2\ell - 2 \) such that \( G' \setminus X' \) contains no \( C \)-path of odd length. This proves (1).

Suppose \( G \) contains no \( \ell \) vertex-disjoint parity-breaking \( C \)-paths with respect to \( H \). By (1), there is \( X \subseteq V(G) \) with \( |X| \leq 2\ell - 2 \) such that \( G \setminus X \) contains no parity-breaking \( C \)-path with respect to \( H \). For convenience, we identify each vertex in \( C \) with its corresponding vertex of \( K_s + I_t \). For distinct \( u, v \in C \), if \( uv \in E(K_s + I_t) \) then let \( Q_{uv} \) be the linking path from \( u \) to \( v \) in \( H \). If \( uv \notin E(K_s + I_t) \), then let \( Q_{uv} \) be a graph with two vertices \( u \) and \( v \) and no edges.

(2) We claim that there is a block \( U \) in \( G \setminus X \) containing at least \( s + t - |X| \) vertices in \( C \setminus X \) and all linking paths in \( H \) between them.

By Observation 4.3, \( G \setminus X \) contains a \((K_a + I_b)\)-subdivision \( K \) such that \( K_a + I_b = (K_s + I_t) \setminus Y \) for some \( Y \subseteq V(K_s + I_t) \) with \( |Y| \leq |X| \) and \( K \) is a subgraph of \( H \). Let \( T \) be the set of all branch vertices in \( K \), where \( |T| \geq a + b = s + t - |Y| \geq s + t - |X| \).

Since \( a \geq s - |Y| \geq 2 \) and \( a + b = s + t - |Y| \geq 3 \), \( K_a + I_b \) is 2-connected. Therefore, \( K \) is 2-connected and all vertices in \( T \) are in the same block of \( G \setminus X \).

(3) We claim that \( U \) is bipartite.

Suppose \( U \) contains an odd-length cycle \( D \). For two distinct vertices \( u, v \in C \cap V(U) \), there are two vertex-disjoint paths in \( U \) joining \( \{u, v\} \) and \( V(D) \) by Menger’s theorem. Using these paths, we obtain both an odd-length path and an even-length path from \( u \) to \( v \) in \( U \). One of those paths is a parity-breaking \( C \)-path with respect to \( H \), contradicting that \( G \setminus X \) has no parity-breaking \( C \)-path with respect to \( H \).

Now we are ready to prove the main theorem of this section.

**Theorem 4.5.** Let \( t \geq 2 \) be an integer and \( G \) a graph. If \( G \) contains no odd \( K_t \) minor and contains a bipartite \( K_{2t-2} + I_t \) subdivision, then there is \( X \subseteq V(G) \) with \( |X| \leq 2t - 4 \) such that \( G \setminus X \) contains a bipartite block \( U \) having at least \( t + 3 \) vertices.

**Proof.** Let \( H \) be a bipartite \( K_{2t-2} + I_t \) subdivision of \( G \), and let \( C = \{v_1, \ldots, v_{3t-2}\} \) be the set of all branch vertices in \( H \). For convenience, we identify each vertex in \( C \) with its corresponding vertex in \( V(K_{2t-2} + I_t) \). Let \( C_1 \subseteq C \) be the set of branch vertices corresponding to vertices in \( K_{2t-2} \), and let \( C_2 = C \setminus C_1 \) be the set of branch vertices corresponding to vertices in \( I_t \).

By Lemmas 4.1 and 4.4, there exists \( X \subseteq V(G) \) with \( |X| \leq 2t - 4 \) such that \( G \setminus X \) has a bipartite block \( U \) containing at least \( (3t - 2) - |X| \) vertices in \( C \setminus X \) and all linking paths between them. Let \( C' \subseteq C \) be those \((3t - 2) - |X| \geq t + 2 \) branch vertices in \( U \), and let \( H' \) be the union of all linking paths between vertices in \( C' \), which is a subgraph of \( U \).

Recall that we identified \( C' \subseteq V(H') \) with \( V(K_{2t-2} + I_t) \). Since vertices in \( C_1 \) form a clique of \( K_{2t-2} + I_t \) and \(|C' \cap C_1| \geq |C'|-|C_2| \geq 2\), the subgraph of \( K_{2t-2} + I_t \) induced by \( C' \) is not
bipartite. To obtain $H'$ from the induced subgraph of $K_{2t-2} + I_t$, we should subdivide edges at least once, because $H'$ is bipartite. Thus $H'$ contains a vertex other than vertices in $C'$, implying $|V(U)| \geq |V(H')| \geq |C'| + 1 \geq t + 3$.

5. Proofs of Theorems 1.3 and 1.5

For a class $\mathcal{F}$ of graphs and an integer $d \geq 0$, a graph $G$ has a $(d, \mathcal{F})$-colouring if there is $f : V(G) \to [d]$ such that $G[f^{-1}(\{i\})]$ is in $\mathcal{F}$ for all $i \in [d]$. A class $\mathcal{F}$ of graphs is closed under isomorphisms if, for all $G \in \mathcal{F}$, every graph isomorphic to $G$ is in $\mathcal{F}$. A class $\mathcal{F}$ of graphs is closed under taking disjoint unions if, for all $G, H \in \mathcal{F}$, the disjoint union of $G$ and $H$ is in $\mathcal{F}$.

Now we are ready to prove the following lemma, following the idea of Kawarabayashi and Mohar [18].

Lemma 5.1. Let $t \geq 2$ and $d \geq 3$ be integers, and let $\mathcal{F}$ be a class of graphs closed under isomorphisms and taking disjoint unions, which satisfies the following.

(i) $\mathcal{F}$ contains every graph with at most $4t - 7$ vertices.

(ii) If a graph $H$ contains no odd $K_t$ minor and no bipartite $K_{2t-2} + I_t$ subdivision, then $H$ has a $(d, \mathcal{F})$-colouring.

Then every graph with no odd $K_t$ minor has a $(d + 4t - 7, \mathcal{F})$-colouring.

Proof. We prove the following stronger claim.

Claim 1. Let $G$ be a graph with no odd $K_t$ minor, $Z \subseteq V(G)$ with $|Z| \leq 4t - 7$, and let $f : Z \to [d + 4t - 7]$ be a colouring. Then $G$ has a $(d + 4t - 7, \mathcal{F})$-colouring $g$ that satisfies the following.

(a) For every $z \in Z$, $f(z) = g(z)$.

(b) For every $v \in Z$ and its neighbour $w \notin Z$, $g(v) \neq g(w)$.

Let $G$ be a counter-example with the minimum $|V(G)| + |E(G)|$. As the claim is true for graphs with at most $4t - 7$ vertices by giving distinct colours to each vertex not in $Z$, $|V(G)| \geq 4t - 6$.

(1) $Z$ is stable.

Suppose there are adjacent $z_1, z_2 \in Z$. Applying the claim on $G' = G \setminus z_1z_2$ with the same $Z$ and $f$, $G'$ has a $(d + 4t - 7, \mathcal{F})$-colouring $g$ that satisfies the claim. We claim that every component of $G[g^{-1}(\{i\})]$ for some $i \in [d + 4t - 7]$ is in $\mathcal{F}$. Let $C$ be a component of $G[g^{-1}(\{i\})]$ for some $i \in [d + 4t - 7]$. If $V(C) \cap Z \neq \emptyset$ then $V(C) \subseteq Z$ by (b), implying $C \in \mathcal{F}$ as $|V(C)| \leq |Z| \leq 4t - 7$. If $V(C) \cap Z = \emptyset$ then $C$ is a component of $G'[g^{-1}(\{i\})]$, which implies $C \in \mathcal{F}$. Therefore, $g$ is a $(d + 4t - 7, \mathcal{F})$-colouring of $G$ satisfying (a) and (b), contradicting our assumption.

(2) For every separation $(A, B)$ of order at most $2t - 3$, we have either $V(A) \setminus V(B) \subseteq Z$ or $V(B) \setminus V(A) \subseteq Z$.

Suppose $G$ has a separation $(A, B)$ of order at most $2t - 3$ such that both $V(A) \setminus V(B) \setminus Z$ and $V(B) \setminus V(A) \setminus Z$ are non-empty. Since $|Z| = |V(A) \cap Z| + |(V(B) \setminus V(A)) \cap Z|$, we may assume $|(V(B) \setminus V(A)) \cap Z| \leq |Z|/2 \leq 2t - 4$. Note that $V(B) \setminus V(A) \setminus Z \neq \emptyset$ implies that $|V(A) \cup Z| < |V(G)|$ and we can apply the claim on $A \cup G[Z]$ with $Z$ and $f$. Let $g_1$ be a $(d + 4t - 7, \mathcal{F})$-colouring of $A \cup G[Z]$ satisfying (a) and (b). Let $Z' = V(A \cap B) \cup (V(B) \cap Z)$. Since $|Z'| = |V(A \cap B)| + |V(B \cap Z)| \geq 2t - 3$, we have either $V(A) \setminus V(B) \subseteq Z$ or $V(B) \setminus V(A) \subseteq Z$.
Therefore, $v_C$ is a component of $C$ having at least $v$ as $g$ satisfies (a) and (b). Let $g$ be a colouring on $V(G)$ such that for each vertex $v$ of $G$,

$$g(v) = \begin{cases} 
g_1(v) & \text{for } v \in V(A), 
g_2(v) & \text{for } v \in V(B). 
\end{cases}$$

This is well-defined since $g_1$ is identical to $g_2$ on $Z$. We claim that $g$ is a $(d + 4t - 7, \mathcal{F})$-colouring of $G$ satisfying (a) and (b), which contradicts our assumption.

By the definition of $g_1$, it follows that $g(z) = g_1(z) = f(z)$ for every $z \in Z$. For every $vw \in E(G)$ with $v \in Z$ and $w \notin Z$, $g(v) \neq g(w)$ since $g_1(v) = g(v) \neq g(w) = g_2(w)$ if $w \in V(A)$ and $g_2(v) = g(v) \neq g(w) = g_2(w)$ if $w \in V(B)$. This verifies (a) and (b).

Let $C$ be a component of $G[g^{-1}([i])])$ for some $i \in [d + 4t - 7]$. If $V(C) \cap Z \neq \emptyset$ then $V(C) \cap (V(A) \setminus Z) = \emptyset$ by the definition of $g_1$ and (b), and $V(C) \cap (V(B) \setminus V(A) \setminus Z) = \emptyset$ by the definition of $g_2$ and (b). This implies $V(C) \subseteq Z$ and thus $C \in \mathcal{F}$ as $|V(C)| \leq |Z| \leq 4t - 7$. If $V(C) \cap Z = \emptyset$ and $V(A) \cap V(B) \cap V(C) = \emptyset$, then either $V(C) \subseteq V(A) \setminus V(B) \setminus Z$ or $V(C) \subseteq V(B) \setminus V(A) \setminus Z$, which implies that $C \in \mathcal{F}$ as $C$ is a component of either $G[g_1^{-1}([i])])$ or $G[g_2^{-1}([i])])$.

(3) $G \setminus Z$ contains a bipartite $K_{2t-2} + I_t$ subdivision.

Since $|Z| \leq 4t - 7$, we may assume $f(Z) \subseteq \{d + 1, \ldots, d + 4t - 7\}$ by permuting colours. Suppose $G \setminus Z$ does not contain a bipartite $K_{2t-2} + I_t$ subdivision. Let $g_0$ be a $(d, \mathcal{F})$-colouring of $G \setminus Z$. Let $g : V(G) \to [d + 4t - 7]$ be a colouring such that for each vertex $v$ of $G$,

$$g(v) = \begin{cases} 
g_1(v) & \text{for every } v \in V(G) \setminus Z, 
g(u) & \text{for every } z \in Z.
\end{cases}$$

We claim that $g$ is a $(d + 4t - 7, \mathcal{F})$-colouring of $G$ satisfying (a) and (b), which contradicts our assumption. Let $C$ be a component of $G[g^{-1}([i])])$ for some $i \in [d + 4t - 7]$. Since $g$ is identical to $g_1$ on $V(G) \setminus Z$ and $g(u) \neq g(v)$ for every $u \in V(G) \setminus Z$ and $v \in Z$, $C$ is a component of either $G[g_1^{-1}([i])])$ or $G[f^{-1}([i])])$. This implies $C \in \mathcal{F}$. This proves (3).

Since $G$ contains a bipartite $K_{2t-2} + I_t$ subdivision, Theorem 4.5 implies that there exists $X \subseteq V(G)$ with $|X| \leq 2t - 4$ such that $G \setminus X$ admits a block decomposition with a bipartite block $U$ having at least $t + 3$ vertices.

(4) Every component of $G \setminus X \setminus V(U)$ is a subgraph of $G[Z]$.

Let $C$ be a component of $G \setminus X \setminus V(U)$. Let $V_C$ be the set of vertices in $U$ adjacent to a vertex in $C$. As $U$ is a block and $C$ is a component of $G \setminus X \setminus V(U)$, it follows that $|V_C| \leq 1$. If $|V_C| = 1$ then let $v_C$ be the unique vertex in $V_C$. Let $A_C = G[V(C) \cup X \cup V_C]$ and $B_C = G \setminus V(C)$. Note that $V(A_C) \cap V(B_C) = X \cup V_C$ and $(A_C, B_C)$ is a separation of $G$ of order at most $2t - 3$, since $|X| + |V_C| \leq 2t - 3$. By (2), either $V(A_C) \setminus V(B_C)$ or $V(B_C) \setminus V(A_C)$ is in $Z$. Since $Z$ is stable, $V(U) \setminus V_C \subseteq V(B_C) \setminus V(A_C)$ and $U$ is 2-connected as $|V(U)| \geq t + 3$, $V(B_C) \setminus V(A_C)$ is not a subset $Z$. Therefore, $V(A_C) \setminus V(B_C) = V(C)$ is a subset of $Z$. This proves (4).

Since $U \setminus Z$ is a bipartite subgraph of $G$, let $X_1, X_2$ be its bipartition. By (4), it follows that $V(G) = Z \cup (X \setminus Z) \cup X_1 \cup X_2$. Let us choose three colours $\{c_1, c_2, c_3\} \subseteq [4t - 4] \setminus f(Z)$. Let $g : V(G) \to [4t - 4] \subseteq [d + 4t - 7]$ be a colouring defined as follows:
We claim that $g$ is a $(d + 4t - 7, F)$-colouring of $G$ satisfying (a) and (b), which contradicts our assumption.

Let $C$ be a component of $G[g^{-1}(\{i\})]$ for some $i \in [d + 4t - 7]$. One of the following cases holds: either $V(C) \subseteq Z$ or $V(C) \subseteq X \setminus Z$ or $V(C) \subseteq X_1$ or $V(C) \subseteq X_2$. Since $|Z|$ and $|X|$ are at most $4t - 7$ and both $X_1$ and $X_2$ are stable in $G$, $C$ is in $F$. \hfill \Box

Now we present proofs of our main theorems.

**Proof of Theorem 1.3.** Let $F$ be the set of graphs of maximum degree at most max $(N(2t - 2, t), 4t - 8)$ where $N$ is in Corollary 2.3. Corollary 2.3 implies that every graph with no bipartite $K_{2t-2} + I_t$ subdivision has a $(2t - 2, F)$-colouring. By Lemma 5.1, $G$ has a $(6t - 9, F)$-colouring, implying that $G$ is $(6t - 9)$-colourable with defect max $(N(2t - 2, t), 4t - 8)$. \hfill \Box

**Proof of Theorem 1.5.** Let $u(t) = C(t, N(2t - 2, t))$ where $C$ is in Theorem 2.5 and $N$ is in Corollary 2.3. Let $F$ be the set of graphs that every component has at most max $(u(t), 4t - 7)$ vertices. By Corollary 2.3 and Theorem 2.5, every graph with no odd $K_t$ minor and no bipartite $K_{2t-2} + I_t$ subdivision has a $(3(2t - 2), F)$-colouring. By Lemma 5.1, $G$ has a $(10t - 13, F)$-colouring, implying that $G$ is $(10t - 13)$-colourable with clustering max $(u(t), 4t - 7)$. \hfill \Box

6. **Concluding remarks**

6.1 **List-colouring variant**

We may consider a list-colouring variant of defective colouring. For integers $s, N \geq 0$, a graph $G$ is $s$-choosable with defect $N$ if, for every set of lists $\{L_v\}_{v \in V(G)}$ with $|L_v| \geq s$ for every $v \in V(G)$, there is a map $f : V(G) \rightarrow \bigcup_{v \in V(G)} L_v$ with $f(v) \in L_v$ for each $v \in V(G)$ such that $G[f^{-1}(\{i\})]$ has maximum degree at most $N$ for every $i \in \bigcup_{v \in V(G)} L_v$.

As we remarked in Section 1, Theorems 2.1 and 2.2 can be extended for list-colourings. For instance, Ossona de Mendez, Oum and Wood [25] showed that for integers $s, t \geq 1$ and every graph $G$ with no $K_{s,t}$ subgraph, there is $N = N(s, t)$ such that $G$ is $s$-choosable with defect $N$. It follows that for $t \geq 1$, every graph with no $K_{t+1}$ minor is $t$-choosable with defect $M$ for some constant $M = M(t)$, which is also implied by the proof of Edwards, Kang, Kim, Oum and Seymour [6].

Note that every $n$-vertex graph with no $K_t$ minor contains $O(t, \sqrt{\log t} n)$ edges [20, 21, 28, 29]. In contrast to graphs with no $K_t$ minor, an $n$-vertex graph with no odd $K_3$ minor may contain $\Omega(n^2)$ edges. For example, complete bipartite graphs have no odd $K_3$ minor.

**Theorem 6.1.** ([Kang [16]]). For each integer $N \geq 0$, there is a function $s = s(d) = (1/2 + o(1)) \log_2 d$ as $d \rightarrow \infty$ such that if a graph $G$ has minimum degree at least $d$, $G$ is not $s$-choosable with defect $N$.

By Theorem 6.1, it follows that for integers $t \geq 1$ and $s, N \geq 0$, there are graphs with no odd $K_t$ minor not $s$-choosable with defect $N$.

6.2 **Extending Theorems 1.3 and 1.5**

We extend our main results to a slightly larger class of graphs. As we mentioned in Section 3, $G$ contains $H$ as an odd minor if and only if a signed graph $(G, E(G))$ contains a signed graph $(H, E(H))$ as a minor. We review the concepts of signed graphs and their minors in the Appendix.
Given \( \Sigma \subseteq E(H) \), we provide alternative characterization for signed graphs \((G, E(G))\) containing \((H, \Sigma)\) as a minor. A signed graph \((G, E(G))\) contains a signed graph \((H, \Sigma)\) as a minor if and only if

1. there exist vertex-disjoint subgraphs \( \{T_u\}_{u \in V(H)} \) in \( G \) which are trees, and
2. a colouring \( \alpha : \bigcup_{u \in V(H)} V(T_u) \rightarrow \{1, 2\} \) such that for every \( u \in V(H) \), every edge in \( T_u \) is bichromatic, and for every edge \( vw \in E(H) \), there is an edge \( e \in E(G) \) that joins \( V(T_u) \) and \( V(T_v) \) where \( e \) is monochromatic if and only if only if \( vw \in \Sigma \).

Note that for every \( \Sigma \subseteq E(K_t) \), a signed graph \((K_{2t}, E(K_{2t}))\) contains \((K_t, \Sigma)\) as a minor. Replacing \( t \) by \( 2t \), Theorem 1.3 implies that for every \( t \geq 2 \) and every \( \Sigma \subseteq E(K_t) \), if \((G, E(G))\) contains no \((K_t, \Sigma)\) as a minor, then \( G \) is \((12t - 9)\)-colourable with defect \( s(2t) \). Theorem 1.5 also implies that for every \( t \geq 2 \) and every \( \Sigma \subseteq E(K_t) \), if \((G, E(G))\) contains no \((K_t, \Sigma)\) as a minor, then \( G \) is \((20t - 13)\)-colourable with clustering \( C(2t) \).

By modifying the proofs in Section 4, we can improve these bounds further. In the proof of Lemma 4.1, we join \( V(M_i) \) and \( V(M_i) \) with a parity-breaking path with respect to \( \alpha \) for \( 1 \leq i < j \leq t \). Because \( \alpha(x_i) = \beta(x_i) \) and \( \alpha(y_i) \neq (y_i) \), we can also join \( V(M_i) \) and \( V(M_i) \) with a path that is not parity-breaking with respect to \( \alpha \). In particular, Lemma 4.1 forces not only an odd \( K_t \) minor, but also a signed \((K_t, \Sigma)\) minor for every \( \Sigma \subseteq E(K_t) \). This extends Theorems 1.3 and 1.5 as follows.

**Corollary 6.2.** For each integer \( t \geq 2 \), there exists an integer \( s = s(t) \) such that for every \( \Sigma \subseteq E(K_t) \) and \((G, E(G))\) with no \((K_t, \Sigma)\) minor, the graph \( G \) is \((6t - 9)\)-colourable with defect \( s \).

**Corollary 6.3.** For each integer \( t \geq 2 \), there exists an integer \( C = C(t) \) such that for every \( \Sigma \subseteq E(K_t) \) and \((G, E(G))\) with no \((K_t, \Sigma)\) minor, the graph \( G \) is \((10t - 13)\)-colourable with clustering \( C \).

### 6.3 Upper bound of maximum degree

In Theorem 2.2, the function \( M(s, t, \delta_1, \delta_2) \) is defined as follows:

\[
M(s, t, \delta_1, \delta_2) = \begin{cases} 
  t - 1 & \text{if } s = 1, \\
  \frac{\delta_2 t (\delta_1 - 2)}{2} + \delta_1 & \text{if } s = 2, \\
  \left(\delta_1 - s\right) \left(\left\lfloor \frac{\delta_2}{s-1}\right\rfloor (t-1) + \frac{\delta_2}{2}\right) + \delta_1 & \text{if } s > 2.
\end{cases}
\]

Therefore, it follows that

\[
N(2t - 2, t) = M(2t - 2, t, O(t^2), O(t^2)) = \exp \left(O\left(t \log t\right)\right)
\]

in Corollary 2.3. Hence we have the upper bound of \( s(t) = \exp \left(O\left(t \log t\right)\right) \) in Theorem 1.3.

If one replaces a bipartite \( K_{2t-2} + I_t \) subdivision of Lemma 4.1 with a bipartite \( K_{3t-2} \) subdivision, one may set \( s(t) = O(t^4) \) since \( N(3t - 3, 1) = O(t^4) \). However, this will increase the number of colours from \( 6t - 9 \) to \( 7t - 10 \) of Theorem 1.3, as graphs with no bipartite \( K_{3t-2} \) subdivision are defectively coloured with \( 3t - 3 \) colours, which is more than \( 2t - 2 \) colours in defectively colouring of graphs with no bipartite \( K_{2t-2} + I_t \) subdivision.

### References

Appendix: Signed graphs

We review elementary concepts of signed graphs, following definitions in [12] and [14] unless stated otherwise.

A signed graph \( (G, \Sigma) \) is a graph \( G = (V, E) \) equipped with a signature \( \Sigma \subseteq E \). To avoid confusion, graphs always denote unsigned graphs. Every signed graph is assumed to be simple; parallel edges and loops are not allowed. If an edge \( e \in E(G) \) is in \( \Sigma \), \( e \) is negative. Otherwise, \( e \) is positive.

For two sets \( A \) and \( B \), \( A \Delta B \) denotes the set \( (A \setminus B) \cup (B \setminus A) \). For a graph \( G \) and \( X \subseteq V(G) \), let \( \delta_G(X) \) be the set of edges joining \( X \) and \( V(G) \setminus X \). For a signature \( \Sigma \), a re-signing on \( X \) is an operation that replaces \( \Sigma \) with another signature \( \Sigma \Delta \delta_G(X) \) for some \( X \subseteq V(G) \). Note that for \( X, Y \subseteq V(G) \), applying re-signing on \( X \) and \( Y \) is identical to applying re-signing on \( X \Delta Y \). In particular, re-signing at \( v \) is the operation that replaces \( \Sigma \) with \( \Sigma \Delta \delta_G(\{v\}) \). Note that applying a re-signing operation on \( X \) is identical to applying re-signing operations at all vertices in \( X \).
Two signatures $\Sigma$ and $\Sigma'$ are equivalent if $\Sigma'$ can be obtained from $\Sigma$ by re-signing operations; $\Sigma$ and $\Sigma'$ are equivalent if and only if there is $X \subseteq V(G)$ such that $\Sigma' = \Sigma \Delta \delta_G(X)$. Two signed graphs $(G, \Sigma)$ and $(G, \Sigma')$ are equivalent if $\Sigma$ is equivalent to $\Sigma'$.

A cycle $C$ is called balanced if it contains an even number of negative edges. Two signed graphs $(G, \Sigma)$ and $(G, \Sigma')$ have the same set of balanced cycles if and only if $\Sigma$ and $\Sigma'$ are equivalent (see [12]).

A map $f : V(G) \to V(H)$ is an isomorphism from $(G, \Sigma)$ and $(H, \Sigma')$ if $f$ is an isomorphism from $G$ to $H$, and $uv \in \Sigma$ if and only if $f(u)f(v) \in \Sigma'$. If there is an isomorphism from $(G, \Sigma)$ to $(H, \Sigma')$, $(G, \Sigma)$ is isomorphic to $(H, \Sigma')$.

For two signed graphs $(G, \Sigma)$ and $(H, \Sigma')$, $(H, \Sigma')$ is a minor of $(G, \Sigma)$ if a signed graph isomorphic to $(H, \Sigma')$ can be obtained from $(G, \Sigma)$ by deleting vertices, deleting edges, applying re-signing operations, and contracting positive edges.

To avoid parallel edges, if we contract a positive edge $uv$ such that there exists a vertex $w \notin \{u, v\}$ and edges $wu, wv \in E(G)$ of different signs, then we should remove either $wu$ or $wv$ before contracting $uv$.

When applying a series of operations to find minors, we may assume that deleting vertices and edges always precede re-signing operations; contracting a positive edge $uv$ into a new vertex $t$ and re-signing at $t$ is identical to re-signing on $\{u, v\}$ and contracting a positive edge $uv$ into a vertex $t$. This implies the following, which can be found in [9].

**Lemma A.1.** For graphs $G, H$ and a signature $\Sigma \subseteq E(H)$, a signed graph $(G, E(G))$ contains a signed graph $(H, \Sigma)$ as a minor if and only if

1. there are vertex-disjoint subgraphs $\{T_u\}_{u \in V(H)}$ of $G$ assigned to vertices in $V(H)$,
2. for every $u \in V(H)$, $T_u$ is a tree and has a proper 2-colouring $c_u : V(T_u) \to \{1, 2\}$, and
3. for every edge $uv \in E(H)$, there is an edge $e = ab \in E(G)$ that joins $T_u$ and $T_v$, such that $c_u(a) = c_v(b)$ if and only if $uv \in \Sigma$.
